Abstract- This paper describes a real-time online prototype driverfatigue monitor. It uses remotely located charge-coupleddevice cameras equipped with active infrared illuminators to acquire video images of the driver. Various visual cues that typically characterize the level of alertness of a person are extracted in real time and systematically combined to infer the fatigue level of the driver. The visual cues employed characterize eyelid movement, gaze movement, head movement, and facial expression. A probabilistic model is developed to model human fatigue and to predict fatigue based on the visual cues obtained. The simultaneous use of multiple visual cues and their systematic combination yields a much more robust and accurate fatigue characterization than using a single visual cue. This system was validated under real-life fatigue conditions with human subjects of different ethnic backgrounds, genders, and ages; with/without glasses; and under different illumination conditions. It was found to be reasonably robust, reliable, and accurate in fatigue characterization.

Keyword: National Highway Traffic Safety Administration (NHTSA), Accelerometer, angle based accelerometer (ACC)

I. INTRODUCTION

This paper describes a real-time online prototype driverfatigue monitor. It uses remotely located charge-coupleddevice cameras equipped with active infrared illuminators to acquire video images of the driver. Various visual cues that typically characterize the level of alertness of a person are extracted in real time and systematically combined to infer the fatigue level of the driver. The visual cues employed characterize eyelid movement, gaze movement, head movement, and facial expression. A probabilistic model is developed to model human fatigue and to predict fatigue based on the visual cues obtained. The simultaneous use of multiple visual cues and their systematic combination yields a much more robust and accurate fatigue characterization than using a single visual cue. This system was validated under real-life fatigue conditions with human subjects of different ethnic backgrounds, genders, and ages; with/without glasses; and under different illumination conditions. It was found to be reasonably robust, reliable, and accurate in fatigue characterization. This paper describes a real-time online prototype driverfatigue monitor. It was found to be reasonably robust, reliable, and accurate in fatigue characterization.

II. CONCEPT

Sleep related accidents tend to be more severe, possibly because of the higher speeds involved and because the driver is unable to take any avoiding action, or even brake, prior to the collision. Horne describes typical sleep related accidents as ones where the driver runs off the road or collides with another vehicle or an object, without any sign of hard braking before the impact. In 2002, the National Highway Traffic Safety Administration (NHTSA) estimated that 35 percent of all traffic deaths occurred in crashes in which at least one driver or no occupant had a BAC (Blood Alcohol Content) of 0.08 percent or more and that any alcohol was present in 41 percent of all fatal crashes in 2002. Such statistics are sometimes cited as proof that a third to half of all fatal crashes are caused by "drunk driving" and that none of the crashes that involve alcohol would occur if the alcohol were not present. But this is incorrect and misleading because alcohol is only one of several factors that contribute to crashes involving drinking drivers. Furthermore, some fatally injured people in alcohol-related crashes are pedestrians with positive BACs, and these fatalities still would occur even if every driver were sober. Distracted driving is a top danger behind the wheel. In fact, about eight out of 10 crashes involve some sort of driver inattention within three seconds of that crash. We've all seen it and likely even done it, driving distracted includes anything

from talking on the phone, to messing with your music, to attending to your children or even pets. All of these actions can lead to serious consequences. Martha Meade with AAA Mid-Atlantic says, "People are dying because of a simple missed phone call, a dropped toy or some other event that is completely not important." Possible techniques for detecting drowsiness in drivers can be generally divided into the following categories: sensing of physiological characteristics, sensing of driver operation, sensing of vehicle response, monitoring the response of driver: available blink detectors in market (Catalog No. 9008 of Enable devices) or we can incorporate it with a special instruction written in image processing that, if there is no pupil found for the certain period of pre-determined i.e. time greater than the human eye blinking time then consider an event called "blink", for which the set of operations will be followed. Here, in this case we need to set time as 1 second or above it, as "blink event" is different from "normal eye blinking". We need to perform testing for only blink event estimation, and not to find normal eye blinking.

Figure1:Module for eye blinks detection

Figure shows the setup of IR sensors & camera module that is to be used by the driver for Eye blink detection, the different blink events which differ from normal blinking of eye using cumulative index (CI) & Mutual index (MI) which is obtained at receiver of IR sensor in terms of Current & voltage and plotted on graph. The signal can be smoothened using above graph to avoid unnecessary blinking event other than effective blinking event.

MOVEMENT DETECTION

Head movement detection is done through single step Accelerometer eg: ADXL330 which measures 3-axis detection. It consists of angle based accelerometer (ACC) input to simulate accurate head movement. Angle based approach does not require any pattern matching algorithms. ACC input signal is smoothened first to ignore any unwanted movement. Angle based

model is believed to be effective by researchers, which is debatable considering practical use of a single ACC sensor on head.

Definition of Tilt Angle

This system uses head movements as the sole input method; more precisely head's tilt angles are used. Head tilt angles define how much the head is rotated along an axis. There are three possible head tilt movements, which are defined as:

- Pitch, the vertical head rotation movement (as in looking up or down)
- Roll, the head rotation that occurs when tilting head towards the shoulders
- Yaw, the horizontal head rotation movement (as in looking to left or right).

Figure2:Three possible head tilt movements

For the movement analysis, it is needed to somehow translate the tilt angle data to displacement of mouse cursor that is calculating new head position. There are two main methods:

when calculating the new head cursor position:

- Absolute mapping in which every tilt angle corresponds to a position on screen.
- Relative mapping in which every tilt angle corresponds to a head displacement amount (stepsize) and this amount is summed by the coordinates of the head's old position, to calculate new position.

Figure3:Accelerometer Placement

Figure shows the real time placement of the accelerometer on the driver head for the 3-axis detection of the head movement while driving to monitor fatigue by converting the angle based input to voltage output (in milivolts) for accurate detection.

Figure4:Block Diagram

COMPONENT DESCRIPTION

We have used following components:

1. ARM processor.
2. Pair of IR transmitter and receiver for eye blinks detection.
3. A sensor called MQ3 for the purpose of alcohol detection.
4. An accelerometer ADXL330 for head movement detection (tilting and turning of head).

ADVANTAGES

- Component establishes interface with other drivers very easily.
- Life of the driver can be saved by locking the ignition system of the car.
- Traffic management can be maintained by reducing accidents and traffic jams can be avoided.
- Using GPS & GSM exact location of the Car can be traced on MAP.

APPLICATION

- Automobiles.
- Security Guard Cabins.
- Operators at nuclear power plants where continuous monitoring is necessary.
- Pilots of airplane.
- Military application where high intensity monitoring of soldier is needed.

FUTURE SCOPE

- This system only looks at the number of consecutive frames where the eyes are closed. At that point it may be too late to issue the warning. By studying eye movement patterns, it is possible to find a method to generate the warning sooner.
- Using 3D images is another possibility in finding the eyes. The eyes are the deepest part of a 3D image, and this maybe a more robust way of localizing the eyes.
- Instead of alarm we can use Automatic Braking System which will reduce the speed of the car.
- We can automatically park the car by first using Automatic braking system, which will slow down the car and simultaneously will turn on the parking lights of the car and will detect the parking space and will automatically park the car preventing from accident.
- Using Pressure sensor on the steering alarm or Automatic braking System can be set in case of drowsiness.
- By using wire-less technology such as CarTalk2000 If the driver gets a heart attack or he is drunk it will send signals to vehicles nearby about this so driver become alert.

RESULTS

Some of the results of eye blink detector through graph are given below:

Figure5:Show Eye Blink

Figure shows the saturation & excursion effects occurred before and after the blinking of eye to smoothen the signal.

Figure6:Eyelid Closure Occurrences

Figure shows the “effective blinking event” for which lid closure is set 40% of closing of eye & above which if eye lid closes the event is occurred. Fig shows the lid closure % versus Time before/after accident meanwhile which the time is used to prevent the accident by using various techniques for eg: Buzzing the Alarm, Making Fake call on drivers mobile, etc using various self developed algorithms.

Figure7: Accelerometer detection using reference angle

Figure shows the head movement detection in which the voltage changes w. r. t change in accelerometer angle. Initially 0V is set at 5° i.e. at neutral position. Change in head movement beyond certain specified limits changes the output voltage & hence head movement is detected.

CONCLUSION

Eye based control will be the future of all types of device control, thus making the operation so comfortable and much easier with less human presence. Several risk operations can be easily performed with this type of application and further research and study on these areas will create a new trend of interacting with machines. Hence, a system to monitor fatigue by detecting eye blink & head movement was developed using self developed algorithms.
